#### Abstract

Consider a symmetric multivariate normal distribution (Rao, 1973; p. 196) with intraclass correlation coefficient $\varrho$. This paper gives optimal tests for $\mathrm{H}_{0}: \varrho=0$ against $\mathrm{H}_{1}: \varrho>0$, when some or none of the maginal parameters are known. The tests are locally most powerful similar and are unbiased whatever be the alternative value of $\varrho$.

AMS Subject Classification: 62 H 10 .
Key words: Intraclass correlation coefficient; Symmetric multivariate normal distributions; Locally most powerful similar tests; Unbiased tests.

## 1. Notation and introduction

Let $g\left(x \mid m, \sigma^{2}, \varrho\right)$ denote the $k$-variate normal density given by

$$
\begin{equation*}
g\left(x \mid m, \sigma^{2}, \varrho\right)=\left(2 \pi \sigma^{2}\right)^{-k / 2}\left|\Sigma_{\varrho}\right|^{-1 / 2} \exp \left\{-(x-M)^{\mathrm{T}} \Sigma_{\varrho}^{-1}(x-M) / 2 \sigma^{2}\right\} \tag{1}
\end{equation*}
$$

where $M=(m, m, \ldots, m)^{\mathrm{T}}, \sigma^{2}>0, \Sigma_{\varrho}=\left(\left(\varrho+(1-\varrho) \delta_{i j}\right)\right), \delta_{i j}$ being the Kronecker delta and $-(k-1)^{-1}<\varrho<1$. This density has been extensively used as a model in multivariate analysis (e.g., see Gleser and Olkin (1969), Rao (1973), Kshirsagar (1972), etc.) Let $X_{1}, X_{2}, \ldots, X_{n}$ be a random sample from the above distribution. In this article we derive locally most powerful similar and unbiased tests of $\mathrm{H}_{0}: \varrho=0$ against $\mathrm{H}_{1}: \varrho>0$ for the cases when some or none of $m$ and $\sigma^{2}$ are known.

We consider one-sided alternatives $\mathrm{H}_{1}: \varrho>0$ (the results for $\varrho>0$ follow analogously). We restrict to one-sided alternatives because in most practical situations the sign of $\varrho$ is known. Also, such a restriction allows us to obtain locally most powerful similar tests of $\varrho=0$ which are globally unbiased, i.e., their unbiasedness holds for every fixed $\varrho, 0<\varrho<1$.

To complete the notation, let $X_{s}=\left(X_{s 1}, X_{s 2}, \ldots, X_{s k}\right)^{\mathrm{T}}, X_{s i}$ denoting the $i$-th component of the vector $X_{s}, \bar{X}$ denote the sample mean vector; $\overline{\bar{X}}$ be the sample grand mean $\bar{X}=\left(\sum_{s=1}^{n} \sum_{i=1}^{k} X_{s i}\right) / n k$, and $\bar{X}_{s}$ be defined by $\bar{X}_{s}=\left(\sum_{i=1}^{k} X_{s i}\right) / k, s=$ $1,2, \ldots, n$. Let

$$
W=\sum_{s=1}^{n} \sum_{i=1}^{k}\left(X_{s i}-\bar{X}_{s}\right)^{2}, \quad B=k \sum_{s=1}^{n}\left(\bar{X}_{s}-\overline{\bar{X}}\right)^{2}
$$

and

$$
T=\sum_{s=1}^{n} \sum_{i=1}^{k}\left(X_{s i}-\overline{\bar{X}}\right)^{2}=B+W
$$

Note that $W /(1-\varrho) \sigma^{2}$ is distributed as $\chi_{n(k-1)}^{2}, B /\{1+(k-1) \varrho\} \sigma^{2}$ is distributed as $\chi_{n-1}^{2}$ and $W$ and $B$ are independent (Rao, 1973).

## 2. Locally most powerful similar and unbiased tests

The structure of the locally most powerful similar test (Spjøtvoll, 1968) in each of the cases mentioned in the previous section is based on the inequality

$$
\begin{equation*}
\sum_{s=1}^{n}\left[\frac{\partial}{\partial \varrho} \ln g\left(x_{s} \mid m, \sigma^{2}, \varrho\right)\right]_{\varrho=0} \geq c(t) \tag{2}
\end{equation*}
$$

where $c(t)$ generically denotes a constant depending on a fixed value $t$ of the sufficient statistic in each case. Verification of regularity conditions in our problem is straightforward though tedious. Unbiasedness of these tests is proved separately for each case.

Now,

$$
\left.\left.\begin{array}{l}
\frac{\partial}{\partial \varrho} \ln g\left(x_{s} \mid m, \sigma^{2}, \varrho\right)=-\frac{1}{2}\left[\left(\operatorname{det} \Sigma_{\varrho}^{-1}\right) \frac{\partial}{\partial \varrho}\left(\operatorname{det} \Sigma_{\varrho}\right)\right. \\
\left.+\frac{1}{\sigma^{2}} \frac{\partial}{\partial \varrho}\left\{\left(x_{s}-M\right)^{\mathrm{T}} \Sigma_{\varrho}^{-1}\left(x_{s}-M\right)\right\}\right], \\
\frac{\partial}{\partial \varrho}\left(\operatorname{det} \Sigma_{\varrho}\right)=-k(k-1) \varrho(1-\varrho)^{k-2}, \\
\frac{\partial}{\partial \varrho}\left\{\left(x_{s}-M\right)^{\mathrm{T}} \Sigma_{\varrho}^{-1}\left(x_{s}-M\right)\right\}=
\end{array}\right]\{1+(k-1) \varrho\}^{2} \sum_{i=1}^{k}\left(x_{s i}-m\right)^{2}\right)
$$

When $\varrho=0$, (4) equals zero and (5) equals $\sum_{s=1}^{n} \sum \sum_{i \neq j=1}^{k}\left(x_{s i}-m\right)\left(x_{s j}-m\right)$. Hence
(2) reduces to

$$
\begin{equation*}
\sum_{s=1}^{n} \sum_{i \neq j=1}^{k} \sum_{s i}\left(x_{s i}-m\right)\left(x_{s j}-m\right) \geq c(t) \tag{6}
\end{equation*}
$$

Case (i): $m$ known, $\sigma^{2}$ unknown.
Assume without loss of generality that $m=0$ and note that $\sum_{s=1}^{n} \sum_{i=1}^{k} x_{s i}^{2}$ is a complete sufficient statistic for $\sigma^{2}$ under $\mathrm{H}_{0}$. The inequality (6) for the locally most powerful similar test can be written as

$$
T_{1}=\frac{\sum_{s=1}^{n}\left(\sum_{i=1}^{k} x_{s i}\right)^{2}}{\sum_{s=1}^{n} \sum_{i=1}^{k} x_{s i}^{2}} \geq c\left(\sum_{s=1}^{n} \sum_{i=1}^{k} x_{s i}^{2}\right) .
$$

Since the distribution of $T_{1}$ is independent of $\sigma^{2}, T_{1}$ is stochastically independent of the complete sufficient statistic $\sum_{s=1}^{n} \sum_{i=1}^{k} x_{s i}^{2}$. Hence the critical region can be written as

$$
\begin{equation*}
T_{1} \geq c \tag{7}
\end{equation*}
$$

Let $Z=\sum_{s=1}^{n}\left(\sum_{i=1}^{k} x_{s i}\right)^{2}$. Then $T_{1}=Z /\{W+(Z / k)\}$ and (7) reduces to

$$
T_{1}^{\prime}=\frac{Z / n k}{W / n(k-1)} \geq \frac{c(k-1)}{(k-c)}=c^{\prime}, \quad \text { say }
$$

Thus $T_{1}^{\prime}$ has the $F$ distribution with $n$ and $n(k-1)$ degrees of freedom under the null hypothesis.

To prove unbiasedness of the test (7) note that

$$
\begin{aligned}
\operatorname{Pr}\left[T_{1} \geq c \mid \mathrm{H}_{1}\right] & =\operatorname{Pr}\left[\left.\frac{Z / k}{W /(k-1)} \geq c^{\prime} \right\rvert\, \mathrm{H}_{1}\right] \\
& =\operatorname{Pr}\left[F_{n ; n(k-1)} \geq \frac{c^{\prime}(1-\varrho)}{\{1+(k-1) \varrho\}}\right] \\
& \geq \operatorname{Pr}\left[F_{n ; n(k-1)} \geq c^{\prime}\right]=\alpha,
\end{aligned}
$$

since $\varrho \geq 0$.
Case (ii): $m$ unknown, $\sigma^{2}$ known.
We can assume without loss of generality that $\sigma^{2}=1$. The complete sufficient statistic for $m$ under $\mathrm{H}_{0}$ is $\overline{\bar{X}}$. Using

$$
x_{s i}-m=x_{s i}-\overline{\bar{X}}+\overline{\bar{X}}-m,
$$

the criterion (6) reduces to

$$
T_{2}=(k-1) B-W \geq c(\overline{\bar{X}}) .
$$

The distribution of $T_{2}$ is independent of $m$; therefore, $T_{2}$ is stochastically independent of $\bar{X}$. Hence the critical region is given by

$$
\begin{equation*}
T_{2} \geq c \tag{8}
\end{equation*}
$$

Statistic $T_{2}$ is a linear combination of two independent $\chi^{2}$ random variables, for which the distribution theory is developed and a computationally convenient form provided in Sen Gupta (1982). Note that $T_{2}$ can also be written as $k B-T$.

Since $T_{2}^{\prime}=T_{2} / n k(k-1)$ is distributed as $\left\{(k-1) \chi_{n-1}^{2}-\chi_{n(k-1)}^{2}\right\} / n k(k-1)$ under the (null) hypothesis, its percentage points can be obtained by numerical integration. These are given in Table 1 for $\alpha=0.10,0.05$ and $0.01, n=5(5) 30$ and $k=2(1) 10$. For large samples, the normal approximation with mean $-(n k)^{-1}$ and variance $2(n k-k+1) / n^{2} k^{2}(k-1)$ may be used.

Table 1

|  | 10 | 0.04273 | 0.06053 | 0.09740 |  | 10 | 0.03196 | 0.04382 | 0.06773 |

If $n=1$, i.e. if we have only one $k$-variate observation from (1), it is easy to see that (8) is equivalent to

$$
W \leq c
$$

where $W$ is $\chi_{k-1}^{2}$ under $\mathrm{H}_{0}$.

To prove unbiasedness of (8) note that

$$
\begin{aligned}
\operatorname{Pr}\left[T_{2} \geq c\right] & =\operatorname{Pr}\left[(k-1) B-W \geq c \mid \mathrm{H}_{1}\right] \\
& =\operatorname{Pr}\left[\{1+(k-1) \varrho\}(k-1) \chi_{n-1}^{2}-(1-\varrho) \chi_{n(k-1)}^{2} \geq c\right] \\
& \geq \operatorname{Pr}\left[(k-1) \chi_{n-1}^{2}-\chi_{n(k-1)}^{2} \geq c\right] \\
& =\operatorname{Pr}\left[(k-1) B-W \geq c \mid \mathrm{H}_{0}\right] \\
& =\alpha .
\end{aligned}
$$

Case (iii): Both $m$ and $\sigma^{2}$ unknown.
In this case, $\bar{X}$ and $T=\sum_{s=1}^{n} \sum_{i=1}^{k}\left(x_{s i}-\bar{x}_{s}\right)^{2}$ are complete and sufficient under $\mathrm{H}_{0}$. The criterion (6) can be written as

$$
T_{3}=\frac{B}{T} \geq c(\tilde{\bar{X}}, T)
$$

Once again the distribution of $T_{3}$ is independent of $m$ and $\sigma^{2}$ and hence $T_{3}$ is stochastically independent of $(\overline{\bar{X}}, T)$. Thus the locally most powerful similar test becomes

$$
\begin{equation*}
T_{3} \geq c \tag{9}
\end{equation*}
$$

Note that, under $\mathrm{H}_{0}, B / T$ has a Beta distribution with parameters $\frac{1}{2}(n-1)$ and $\frac{1}{2} n(k-1)$, hence the critical value of $T_{3}$ can be easily obtained.

Unbiasedness is proved in a manner similar to case (i).
Case (iv): Both $m$ and $\sigma^{2}$ known.
It can be assumed without loss of generality that $m=0$ and $\sigma^{2}=1$. From (6) the locally most powerful test is given by

$$
\begin{equation*}
T_{4}=\sum_{s=1}^{n} \sum_{i \neq j=1}^{k} x_{s i} x_{s j} \geq c \tag{10}
\end{equation*}
$$

Statistic $T_{4}$ gives the 'best natural unbiased estimator' of $\varrho$ (Sen Gupta, 1982). Distribution of $T_{4}$ is expressible in terms of the well-tabulated Kummer function (Sen Gupta, 1982) or under $\mathrm{H}_{0}$ as

$$
\left\{(k-1) \chi_{n}^{2}-\chi_{n(k-1)}^{2}\right\} / n k(k-1) .
$$

Table 2 gives the percentage points of $T_{4}^{\prime}=T_{4} / n k(k-1)$ for $\alpha=0.10,0.05$ and $0.01, n=5(5) 30$ and $k=2(1) 10$, obtained as in case (ii). For large values of $n$, the distribution of $T_{4}^{\prime}$ can be approximated by the normal distribution with mean zero and variance $2 / n k(k-1)$.

Unbiasedness is proved in a manner similar to case (ii).

Table 2
Percentage points of $T_{4}^{\prime}$

| $n$ | $k$ | $\alpha=0.10$ | 0.05 | 0.01 |  | $n$ | $k$ | $\alpha=0.10$ | 0.05 | 0.01 |
